

A Fishy Example I

- “Sorting incoming Fish on a conveyor according to species using optical sensing”

- Salmon or Sea Bass?

● Problem Analysis

- Set up a camera and take some sample images to extract features
 - Length
 - Lightness
 - Width
 - Number and shape of fins(yüzgeç)
 - Position of the mouth, etc...

This is the set of all suggested features to explore for use in our classifier!

Solution by Stages

- Preprocess raw data from camera
 - Segment isolated fish
 - Extract features from each fish (length,width, brightness, etc.)
 - Classify each fish
- 

● Preprocessing

- Use a segmentation operation to isolate fishes from one another and from the background
- Information from a single fish is sent to a **feature extractor** whose purpose is to reduce the data by measuring certain features
- The features are passed to a **classifier**

Classification

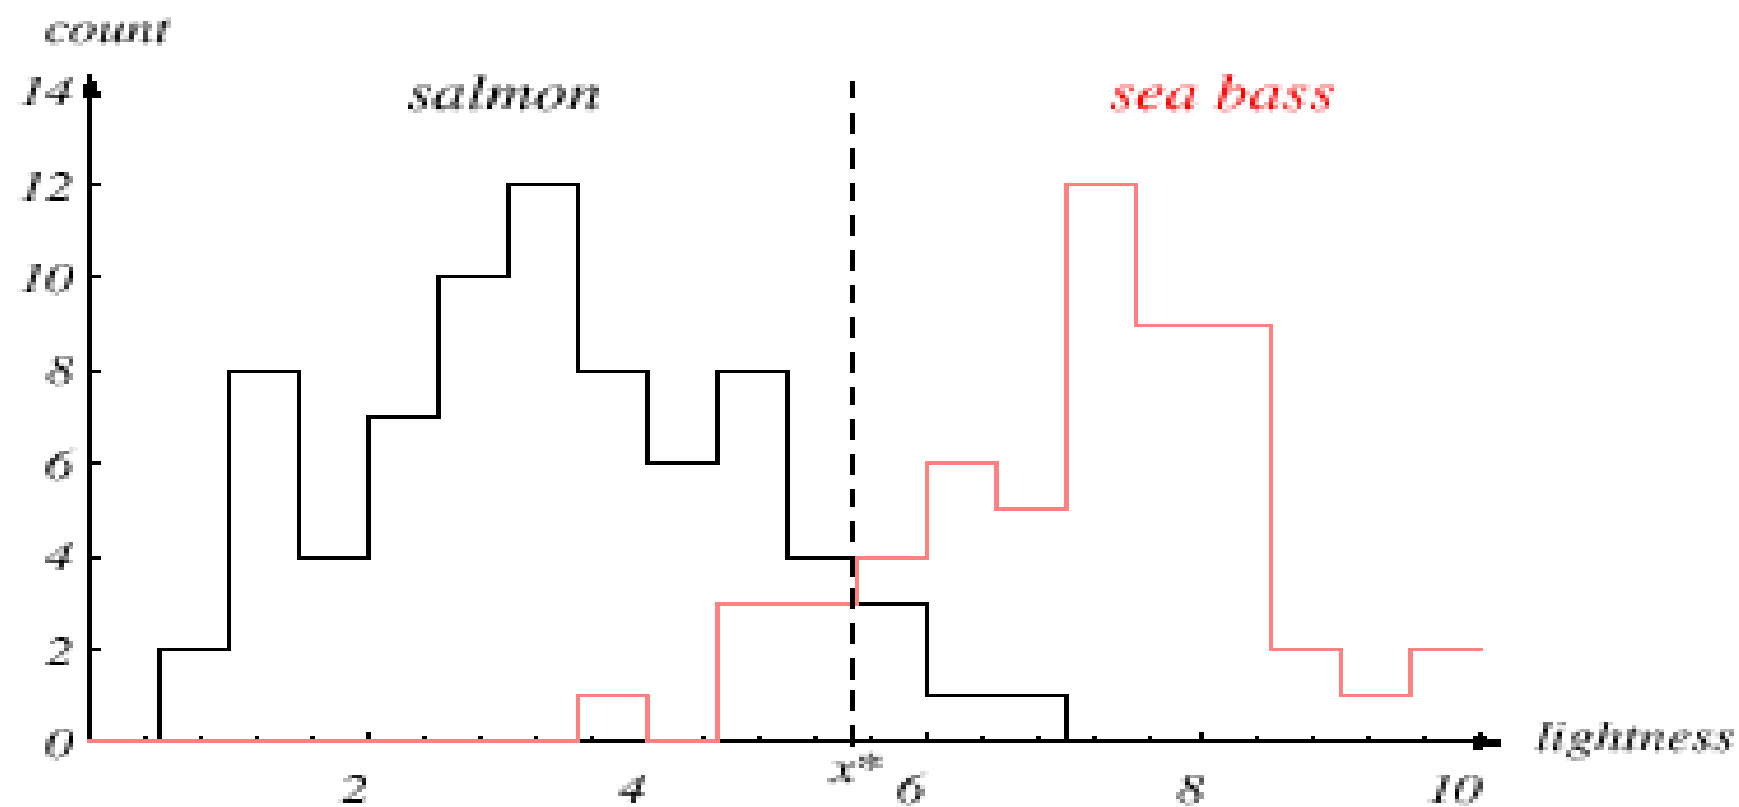

Select the length of the fish as a possible feature for discrimination

The **length** is a poor feature alone!

Select the **lightness** as a possible feature.

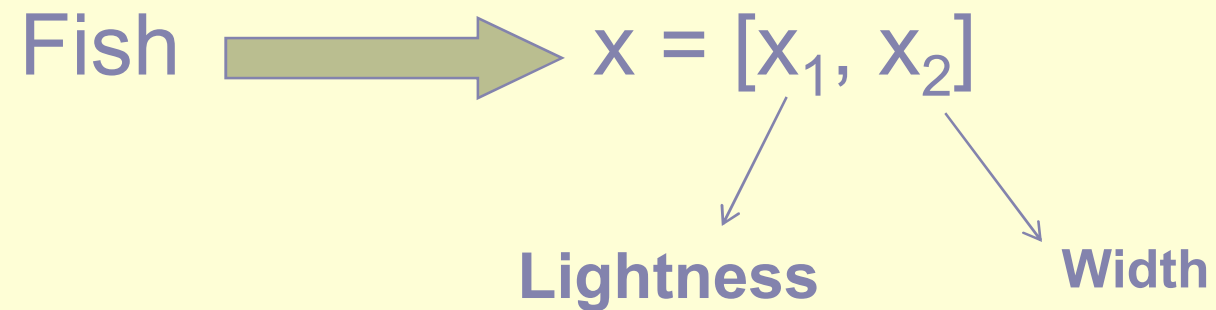

“Customers do not want sea bass in their cans of salmon”

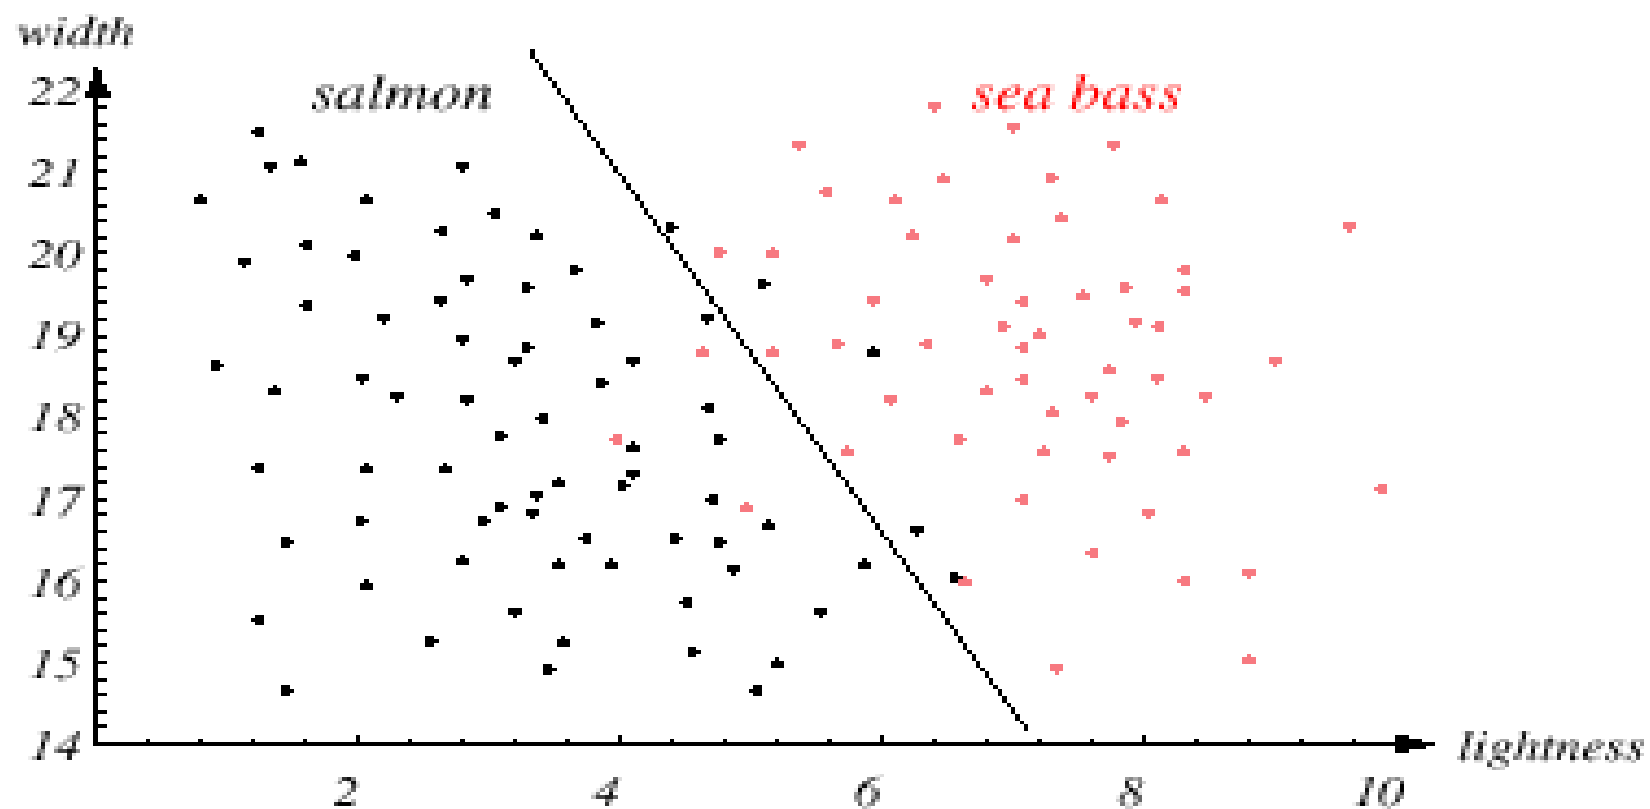

- Threshold decision boundary and cost relationship
- Move our decision boundary toward smaller values of lightness in order to minimize the cost (reduce the number of sea bass that are classified salmon!)

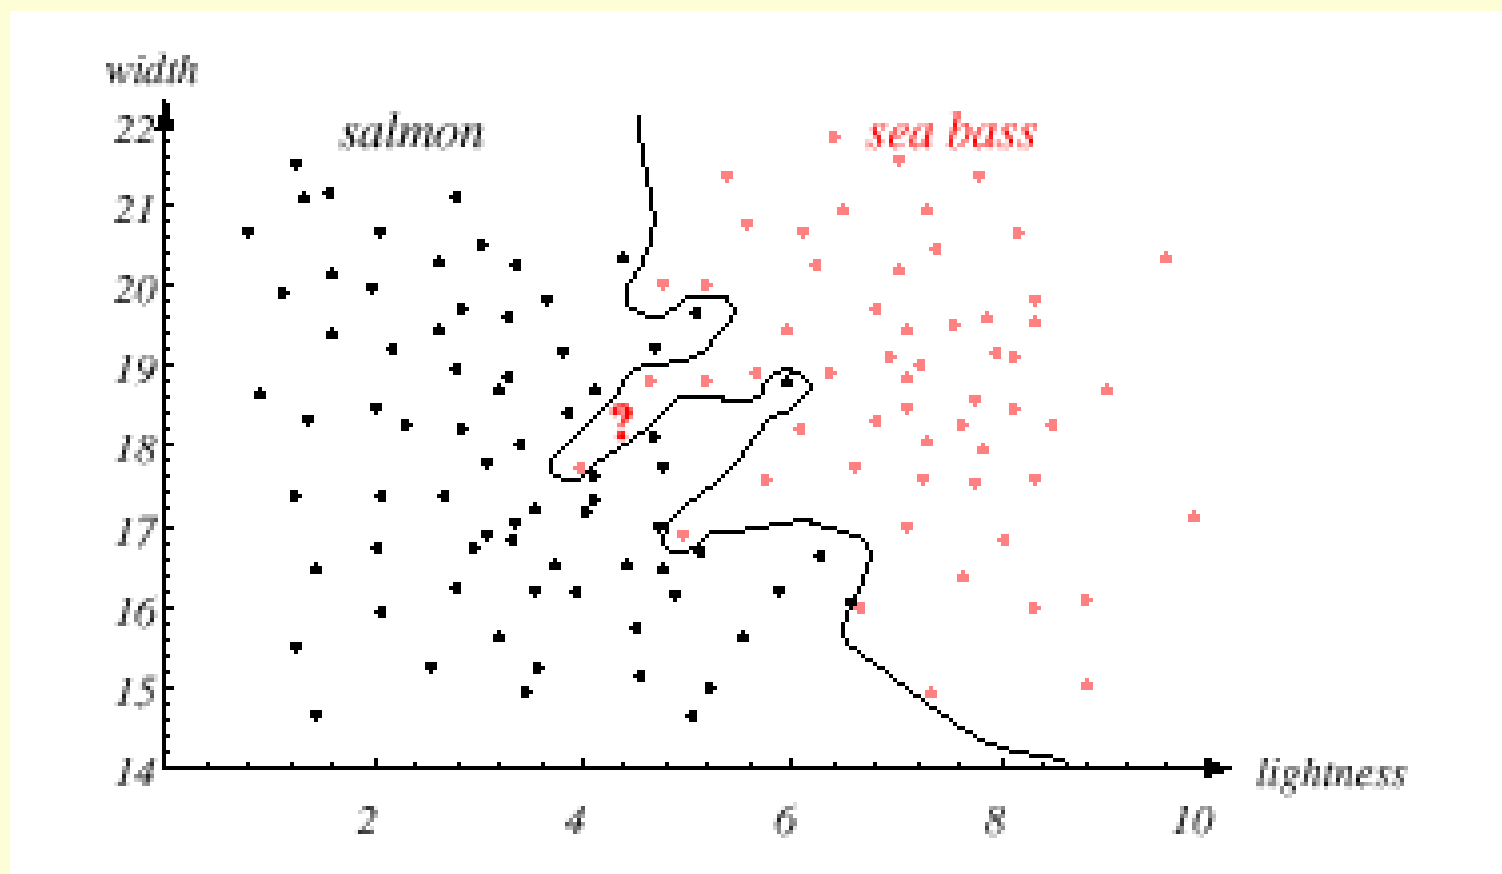

Task of decision theory

- Adopt the lightness and add the width of the fish

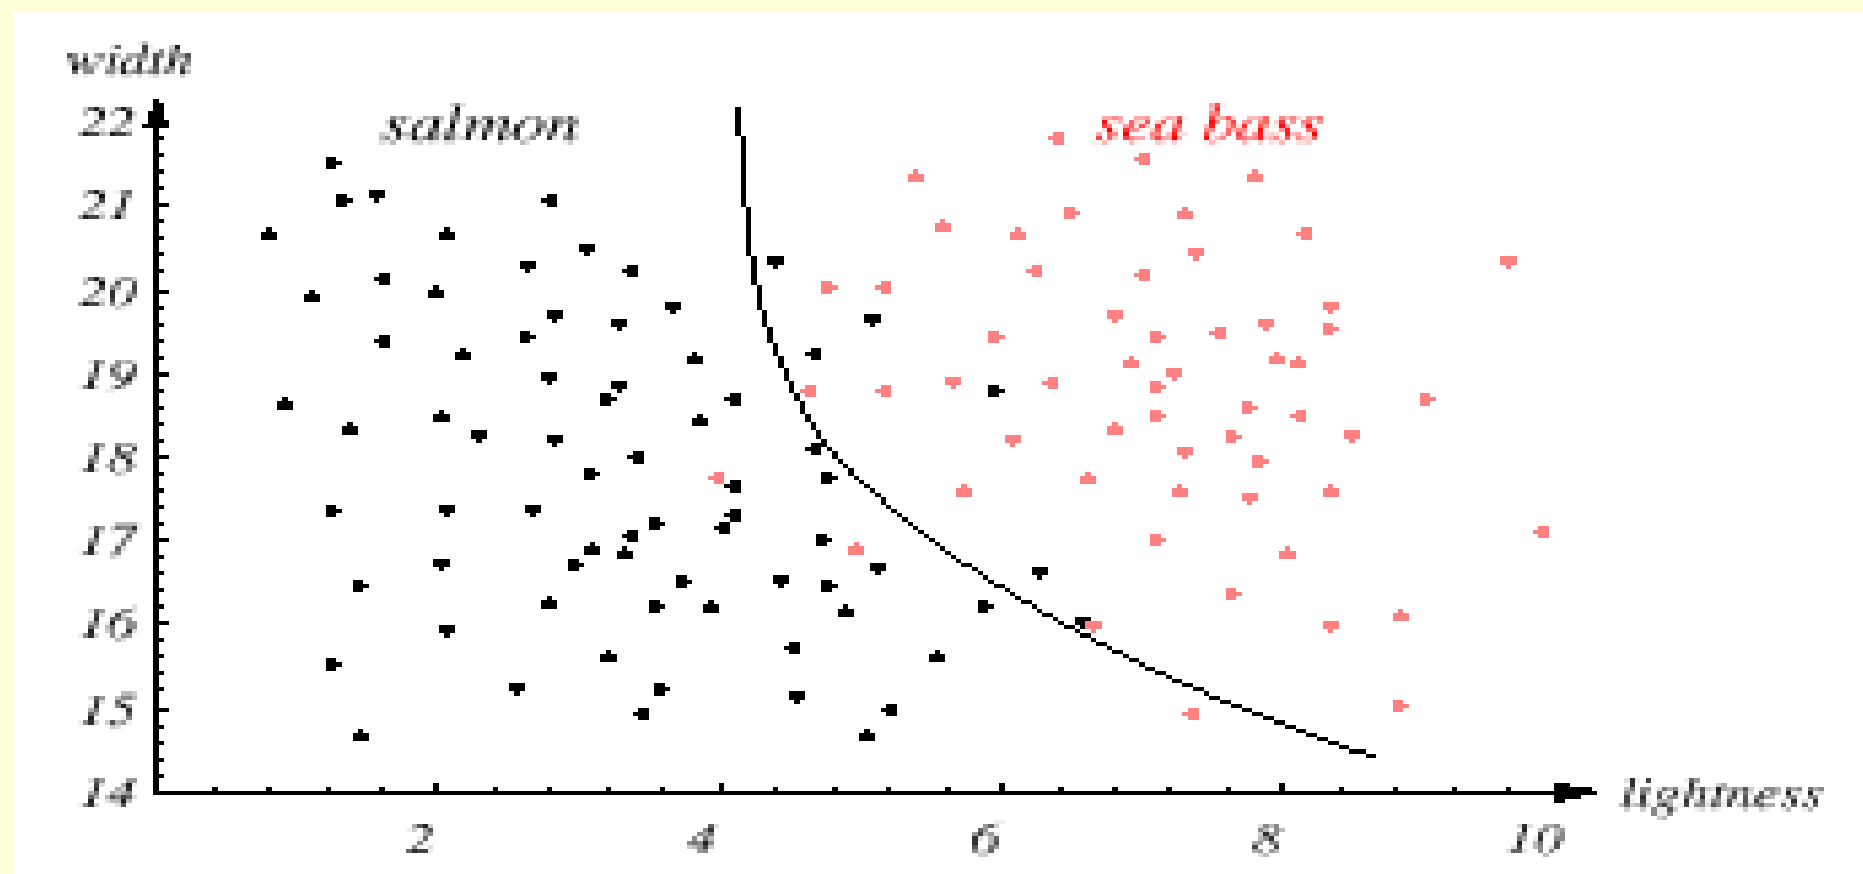

- 
- We might add other features that are not correlated with the ones we already have. A precaution should be taken not to reduce the performance by adding such “noisy features”
 - Ideally, the best decision boundary should be the one which provides an optimal performance such as in the following figure:

- 
- However, our satisfaction is premature because the central aim of designing a classifier is to correctly classify novel input

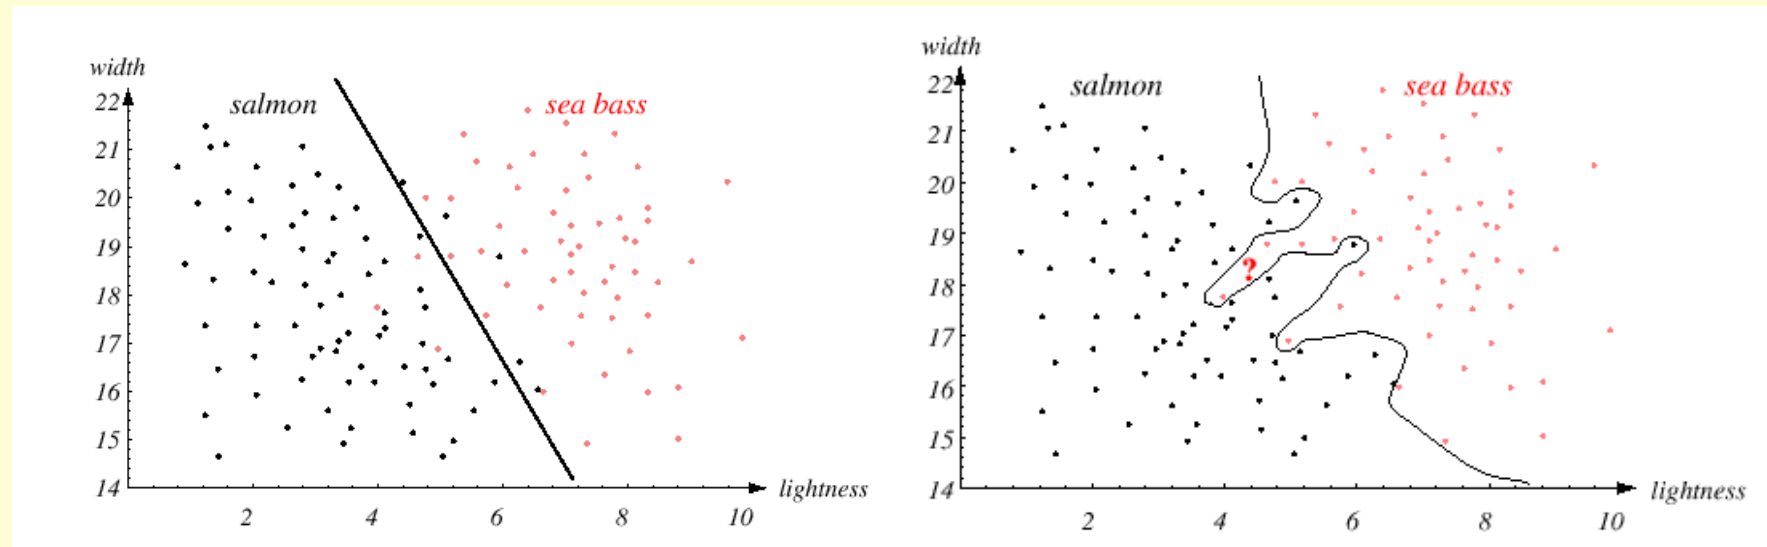

Issue of generalization!

Decision Boundaries

Observe: Can do much better with two features

Caveat: overfitting!

A Complete PR System
